Objective:

To detail the clinical and histopathological findings of a rare IgG4 related ophthalmic disease mimicking eyelid sebaceous carcinoma.

Method:

A case report

Result:

A 75-year-old female with a left upper eyelid mass was referred to The Cancer Institute Hospital of JFCR (Japanese Foundation for Cancer Research). The patient presented with a lesion suspicious for sebaceous carcinoma of the eyelid. An incisional biopsy was performed, and the specimen revealed the diagnosis of IgG4 related ophthalmic disease.

Conclusion:

This case illustrates that IgG4 related ophthalmic disease may mimic sebaceous carcinoma.
